# Fact-Checking Freedom 250: Is Washington Actually Getting Safer and More Beautiful?

Environment * Public Health * Ethics

## Introduction: Evaluating the "Making D.C. Safe and Beautiful" Initiative

The intersection of urban rehabilitation, federal land management, and public policy has come under intense scrutiny during preparations for the United States Semiquincentennial in 2026. Central to these preparations is the "Making D.C. Safe and Beautiful" initiative, stemming from an Executive Order issued on March 28, 2025. This directive mandates a rapid overhaul of the physical, environmental, and social infrastructure of Washington, D.C., targeting areas administered by the National Park Service (NPS), the Department of the Interior (DOI), and the United States Park Police.

Public discourse surrounding these federal interventions has centered on official infographics reporting twelve headline metrics: 1,695 lights repaired, 1,143 benches rehabilitated, 500 graffiti instances cleaned, 45 monuments and 28 statues sanitized, 22 fountains repaired, 6 statues installed, 250 truckloads of debris dredged from the Constitution Gardens Carp Pond, 150.5 tons of pothole repair material applied, 134 rat-resistant trash cans installed, and 152 homeless encampments removed. Driven by the "Freedom 250" commission -- which organized Semiquincentennial events on civic parkland including the INDYCAR Freedom 250 Grand Prix on the National Mall, the Great American State Fair, Rodeo 250, a White House lawn combat sports event, and a July 4th National Special Security Event (NSSE) celebration and fireworks display -- these operational statistics reflect an accelerated federal campaign. This report evaluates the empirical veracity of these claims across materials conservation, aquatic restoration, civil engineering, urban vector ecology, criminology, and fiscal resource allocation.

## Infrastructural Utilities, Stone Conservation, and Aquatic Restoration

Inspection of NPS maintenance logs confirms the physical veracity of the reported utility and monument interventions. Restoring 1,695 municipal lights -- transitioning legacy high-pressure sodium lamps to calibrated light-emitting diode (LED) fixtures -- enhances nighttime pedestrian visibility while reducing municipal energy draw. Similarly, the rehabilitation of 1,143 wood and cast-iron benches by NPS historic tradespeople at sites such as Dupont Circle preserves historic park furniture rather than replacing it with synthetic substitutes.

The sanitization of 500 graffiti sites, 45 monuments, and 28 statues -- including the Lincoln Memorial Reflecting Pool and the Christopher Columbus Memorial Fountain -- relied on materials-conservation chemistry to protect porous marble, limestone, and granite substrates. Rather than applying acidic washes or sodium hypochlorite

bleach, which introduce soluble salts that crystallize during wet-dry cycles and cause subsurface spalling and exfoliation (Charola & Price, 1998)[2], NPS conservationists applied D/2 Biological Solution. Formulated with pH-neutral, salt-free quaternary ammonium compounds, this biocide eradicates biofilms (algae, lichens, and molds) and atmospheric particulates without compromising stone integrity or leaching persistent toxins into adjacent turfgrass.

| Intervention Category | | Claimed Metric | | Objective Veracity | | Underlying Scientific / Structural Context |

| Public Utilities | | 1,695 lights fixed; 1,143 benches rehabbed | | True | | Improves nighttime safety and pedestrian utility; emphasizes historic preservation of existing park furniture. |

| Sanitation & Aesthetics | | 500 graffiti instances cleaned | | True | | Restores visual compliance using specialized chemical agents to lift pigments without abrasive damage. |

| Monument Conservation | | 45 monuments / 28 statues cleaned | | True | | Utilizes D/2 Biological Solution (quaternary ammonium compounds) to safely remove biofilms without introducing destructive soluble salts. |

| Commemorative Additions | | 6 statues installed | | True | | Permanently alters the commemorative landscape in alignment with the Freedom 250 historical narrative. |

In aquatic management, hauling 250 truckloads of sediment and organic debris from the 6.75-million-gallon artificial lake at Constitution Gardens addresses decades of chronic eutrophication. Originally constructed for the 1976 Bicentennial, the shallow, uncirculated basin accumulated urban nitrogen and phosphorus runoff, driving toxic cyanobacteria blooms and severe biological oxygen demand spikes. Paired with the Phase 2 reconstruction led by the NPS and the Trust for the National Mall -- which deepens the basin to stabilize thermal stratification, establishes diverse benthic macrophytes, and installs mechanical and biological filtration -- this dredging restores a self-sustaining aquatic habitat. Concurrently, the reconstruction of the subsiding Tidal Basin seawall halted daily brackish inundation along pedestrian walkways; although construction required removing 306 salt-damaged cherry trees, replanting 426 saplings (including 250 donated by Japan) yielded a net expansion of the local urban carbon sink and tree canopy.

## Pavement Engineering and Urban Rodent Vector Ecology

Across the 265 miles of NPS-managed roadways -- including the George Washington and Baltimore-Washington Parkways -- crews applied 150.5 tons of pothole patching material. Potholes form through freeze-thaw hydraulic wedging: water infiltrating micro-fissures expands by ~9% upon freezing, fracturing the pavement matrix before vehicular loads excavate the cavity. While rapid patching with conventional petroleum-based hot mix asphalt (HMA) eliminates immediate vehicular and hydroplaning hazards, petroleum bitumen undergoes oxidative aging and low-temperature embrittlement while emitting volatile organic compounds (VOCs) and greenhouse gases. Civil engineering research increasingly favors bio-asphalt modifiers derived from biomass pyrolysis and iron-rich biochar or montmorillonite

nanocomposites, which sequester carbon, adsorb paving VOCs, and improve low-temperature fracture resistance (Abe et al., 2022)[1].

On the National Mall, installing 134 rat-resistant trash receptacles with self-closing mechanical baffles represents a scientifically grounded intervention in public health and urban food-web management. Open receptacles subsidize brown rat (Rattus norvegicus) carrying capacity. Historically, municipal agencies combated rodent surges with second-generation anticoagulant rodenticides (SGARs), which bioaccumulate in predatory raptors (red-tailed hawks, barred owls) and urban mesocarnivores, triggering lethal secondary poisoning and a destabilizing trophic cascade across the urban ecosystem (Nakayama et al., 2019)[4]. Physical exclusion lowers rodent carrying capacity without introducing persistent food-web toxicants.

## Law Enforcement Metrics and Encampment Clearances

Under the Making D.C. Safe and Beautiful Task Force, federal authorities invoked the Home Rule Act to coordinate U.S. Park Police and National Guard deployments, reporting 11,756 arrests, 1,278 recovered illegal firearms, and the clearance of 152 unhoused encampments. While removing 1,278 illegal firearms tangibly reduces lethal violence risk, attributing the reported 60% drop in homicides and 68% drop in carjackings solely to the federal surge omits crucial baseline context: Department of Justice criminological data demonstrates that District violent crime had already declined 35% year-over-year to a 30-year low prior to the intervention.

| Task Force Metric | | Reported Statistic | | Contextual Analysis and Implications |

| Total Arrests | | 11,756 | | Reflects a broad, indiscriminate surge in policing; encompasses both violent felonies and minor "quality-of-life" infractions. |

| Firearms Recovered | | 1,278 | | Represents a verifiable, objective improvement in physical public safety by removing deadly weaponry. |

| Violent Crime Reduction | | Homicides (-60%), Carjackings (-68%) | | Statistically accurate for the intervention period, but obscures the fact that macro-level violent crime was already at a 30-year low prior to the operation. |

| Encampment Clearances | | 152 camps removed | | Achieves immediate aesthetic sanitation of federal parks, but creates negative externalities by displacing vulnerable populations to adjacent, underfunded counties. |

Similarly, while clearing 152 homeless encampments restores visual order to federal parkland, empirical public health literature demonstrates that forced displacement without permanent supportive housing fragments continuum-of-care medical access and shifts social service burdens onto adjacent municipalities such as Montgomery County, Maryland (Mayer et al., 2024)[3].

## Fiscal Architecture: FLREA Fee Diversion and Opportunity Costs

Although the DOI announced a five-year, $345 million historic preservation plan alongside corporate sponsorships -- such as a $1 million ScottsMiracle-Gro contribution to restore the White House South Lawn following a combat sports event -- congressional inquiries revealed that immediate D.C. beautification relied on

diverting at least $90 million from Federal Lands Recreation Enhancement Act (FLREA) entrance fee revenues ($76 million for capital repairs and $1.6 million for July 4th pyrotechnics).

| Financial Allocation Category | | Capital Amount | | Funding Source / Mechanism | | Economic Implication |

| Broad 5-Year Preservation Plan | | $345 Million | | DOI Federal Appropriations | | Represents a planned, long-term capital investment in national historic sites. |

| D.C. Rapid Beautification Projects | | $76 Million | | Diverted FLREA Fee Revenues | | Results in a direct loss of deferred maintenance funding at regional and western national parks. |

| Semiquincentennial Fireworks | | $1.6 Million | | Diverted FLREA Fee Revenues | | An unprecedented expenditure, five times the historical average, utilizing funds meant for park conservation. |

| Post-Event Turf Restoration | | $1.0 Million | | Corporate Sponsorship (ScottsMiracle-Gro) | | Demonstrates reliance on private capital to subsidize the environmental damage of large-scale, privately run events on public land. |

Statutorily, FLREA retains 80% of recreation fees at the collecting park and pools 20% for fee-free units. Redirecting centralized FLREA reserves to Washington, D.C. amid a $24 billion national NPS deferred maintenance backlog froze regional contingency funds for wastewater, trail, and structural repairs across western and rural national parks, while mega-events such as the INDYCAR street race introduced acute localized soil compaction and particulate (PM2.5) and NOx emissions.

## Conclusion: Empirical Gains Versus Systemic Externalities

An objective audit of the "Making D.C. Safe and Beautiful" infographic confirms that the physical, chemical, and ecological interventions -- from pH-neutral quaternary ammonium monument conservation (Charola & Price, 1998)[2] and Constitution Gardens lake restoration to mechanical rodent exclusion that prevents anticoagulant rodenticide bioaccumulation across urban food webs (Nakayama et al., 2019)[4] -- are empirically verifiable and technically sound. Restoring 1,695 lights, rehabilitating 1,143 historic benches, patching roadways with 150.5 tons of asphalt, and removing 1,278 illegal firearms deliver tangible improvements to municipal infrastructure and pedestrian utility. However, these localized physical gains are accompanied by omitted criminological baselines showing violent crime had already reached a 30-year low, regional public-health externalities resulting from the forced displacement of 152 unhoused encampments into neighboring counties (Mayer et al., 2024)[3], and the regressive reallocation of $90 million in FLREA national park entrance fee revenues away from deferred maintenance at rural and western parks to subsidize Semiquincentennial events in the capital.

Updates... (Nov 20, 2026): Verified all four peer-reviewed DOIs against CrossRef, standardized numbered reference anchors, and confirmed completed timelines for the June-August 2026 Semiquincentennial events in Washington, D.C.
